Abstract: The reactions of the lithium enolate of acetaldehyde, LioCHCH $_2^n$, with hexachlorocyclotriphosphazene, $N_3^nP_3^nC1_6^n$, lead to the series of vinyloxychlorocyclotriphosphazenes, $N_3^nP_3^nC1_{6-n}^n$ (OCH=CH $_2^n$)(n = 1-6). Evidence for the occurrence of all possible geometrical and positional isomers in the series has been obtained from the $\frac{31}{1}$ P nmr spectra. The principal products are the non-geminal species with comparable amounts of cis and trans isomers being formed. Small amounts of the geminal isomers are also observed. The mono- and pentakis substituted derivatives have been converted to their dimethylamino derivatives, $N_3^nP_3^n(\text{OCH=CH}_2)_{6-n}^n[N(\text{CH}_3)_2^n]_n^n$ (n = 1,5).

Introduction

Although there have been extensive investigations into the reactions of amines 1-3 and more recently of organometallic reagents 4 with cyclophosphazenes, the corresponding reactions with alcohols have received considerably less attention. Detailed studies of the substitution pattern followed in the reactions of phenoxide and the trifluoroethoxide ions with hexachlorocyclotriphosphazene, N₃P₃Cl₆, have appeared. Less detailed studies of the reactions of other selected alkoxides with $N_3P_3Cl_6$ have also been carried out. 7 In all cases a non-geminal pathway is preferred. Recently, we have shown that the ambident enolate anions undergo reactions with the hexahalocyctriphosphazenes, $N_3P_3X_6$ (X = F,C1), to yield the vinyloxypentahalocyclotriphosphenes, $N_3P_3X_5$ OCR=CH₂. 8 The favorable combination of the hard acid (phosphorus (V)) with the hard base (oxygen) leads to exclusive attack at the oxygen end of the enolate anion and thus provides a route to previously inaccessible vinyl alcohol derivatives. In this paper, we present the synthesis and characterization of the series of vinyloxychlorocyclotriphosphazenes, $N_3P_3C1_{6-n}(OCH=CH_2)_n$ (n = 1-6). This study is of interest in terms of exploring the substitution pathway of oxygen based nucleophiles with cyclophosphazenes. These materials are also new organofunctional phosphazenes which can serve as precursors to new monomeric and polymeric phosphazene derivatives.

Experimental:

Hexachlorocyclotriphosphazene, $N_3P_3Cl_6$, (Ethyl Corp.), was recrystalized from petroleum ether to a constant m.p. 113°C. n-Butyl lithium (1.6 M solution in hexane) was obtained from Aldrich. Tetrahydrofuran (THF) (Aldrich) was distilled from sodium-benzophenone ketyl. Petroleum ether (b.p. 35-55°C), benzene 10 and ethyl acetate (Fisher) were distilled by standard procedures. NMR spectra (in CDCl₂) were recorded on a Brücker WM 250 spectrometer operating at 250.1 MHz (1 H), 62.9 MHz (13 C) and 101.2 MHz (31 P). Tetramethylsilane (TMS) was used as internal reference for ¹H and ¹³C NMR measurements. For ³¹P NMR, 85% $\mathrm{H_{3}PO}_{\Lambda}$ was used as an external standard. Chemical shifts upfield to the reference are assigned a negative sign. 13 C and 31 P NMR spectra were recorded under conditions of broad band decoupling. Infrared (IR) spectra were obtained as their thin films (NaCl disks) on a Beckman IR 20A spectrometer. Mass spectra were recorded on a Perkin Elmer RMU - 6D spectrometer operating at 80eV. Elemental analyses were performed by Integral Microanalytical Laboratories. The NMR spectra of mixtures were simulated using a locally modified version of the computer program DNMR3. 11 The "spectral vector output" (i.e. an intensity parameter) of DNM3 was modified to accommodate the calculation of spectra composed on several overlapping subspectra.

Preparation of N₃P₃Cl₅OCH=CH₂(1) and N₃P₃Cl₂(OCH=CH)₂ (2).

A solution of 10.5g (30.2 mmol) of $N_3P_3Cl_6$ was treated with 70.0 mmol of LiOCH=CH₂. A 2 gm sample of the product was separated by flash chromatography to yield 0.92 gm (44.3% of theory) of $N_3P_3Cl_5^{OCH=CH}_2$ (1) as previously described. Continued elution from the column yielded 0.70g (32.80% theory) of a colorless liquid, b.p. 55-57°C at 0.02 mm Hg. Anal. Cacld. for $C_4H_6Cl_4N_3O_2P_3$ (2):

Preparation of N₃P₃Cl₃(OCH=CH₂)₃ (3) and N₃P₃Cl₂(OCH=CH₂)₄ (4).

The lithium enolate prepared from n-C₄H₉Li (45 ml,72 mmol) and THF (80 ml) was added to a solution of N₃P₃Cl₆ (7.5g, 21.7 mmol) in THF (70 ml) at room temperature. The reaction mixture was stirred for five days and worked up as before to give 7.0g of a pale yellow liquid. A 2.0 g sample of this liquid was purified using flash chromatography. The following compounds were obtained in succession: N₃P₃Cl₅OCH=CH₂ (1), 0.15g (6.71% of theory), N₃P₃Cl₄(OCH=CH₂)₂ (2), 0.35g (15.34% of theory). The third compound eluted was distilled under reduced pressure to yield 0.40g (17.18% of theory) of a colorless liquid b.p. 90° C at 0.05 mm Hg. Anal. Calcd. for C₆H₉Cl₃N₃O₃P₃ (3): C, 19.43; H, 2.43; mol. wt. 369. Found: C, 19.12; H, 2.41; mol. wt. 369 (mass spectrum).

¹H NMR: ¹⁴ δΞP-O-CH=CH₂ = 6.6-6.4 (complex multiplet); δΞP-O-CH=CH₂ (trans)=5.1-5.0 (complex multiplet); δΞP-O-CH=CH₂ (cis) = 4.8-4.6 (complex multiplet). ³¹P NMR: ¹⁶ δΞPC1₂ = 27.3, δΞPC1(OCH=CH₂): 18.0, δΞP(OCH=CH₂)₂ = 3.0. Preparation of N₃P₃C1(OCH=CH₂)₅(5) and N₃P₃(OCH=CH₂)₆(6)

The reaction of the lithium enolate prepared from n-C₄H₉Li (85 ml, 136 mmol) and THF (160 ml) with N₃P₃Cl₆ (6.0g, 17.2 mmol) in THF (100 ml) was carried out as described above to yield 5.6g of a pale yellow liquid. A 1.0g sample of this liquid was purified using flash chromatography with petroleum ether - ethyl acetate (97/3) as the eluant. The first product obtained was a viscous liquid which was distilled under reduced pressure to give 0.36g (30.78% of theory) of a colorless liquid, b.p. 105°C at 0.05 mm Hg. Anal. Calcd. for C₁₀H₁₅ClN₃O₅P₃ (5): C, 31.13; H, 3.89; mol. wt., 385. Found: C, 30.39, H, 3.70; mol. wt. 385 (mass spectrum).

Results and Discussion

There are two possible routes of reaction for an ambident enolate anion leading to derivativization of either the oxygen end or the carbon end of the nucleophile. 17 We have previously shown that the phosphazene is attacked by the oxygen end of the enolate anion in the formation of the monosubstituted derivatives. 8 The 1H and 13C nmr spectra of all the new compounds reported in this investigation closely resemble those of the monosubstituted derivative. In particular, the proton spectra resemble

vinylacetate with additional phosphorus coupling and there are no alkyl or carbonyl carbon atoms observed in the 13 C nmr spectra. 18 The nmr spectra of authentic phosphazenes with β -carbonyl functions (the hyopthetical product resulting from the attack on the carbon end of the enolate) have recently been reported and differ significantly from the products of the enolate anion reactions. 19 Consequently, we may conclude that the reaction generally leads to the vinyloxy derivatives as shown below. These materials are stable to air and atmospheric moisture.

$$N_3P_3C1_6 + nLiOC_2H_3 \longrightarrow N_3P_3C1_{6-n} (OCH=CH_2)_n + nLiC1_{n=1-6}$$

The monosubstituted derivative, $\frac{1}{6}$, has an AB $_2$ ³¹P nmr spectrum appropriate to the proposed structure. Further characterizational details were previously reported. ⁸ The chlorine atoms in $\frac{1}{6}$ were removed by the reaction of $\frac{1}{6}$ with dimethylamine to give $N_3P_3[N(CH_3)_2]_5OCH=CH_2$. The $\frac{1}{6}$ H and $\frac{31}{6}$ P nmr spectra of this derivative are consistent with the formulation given above. The fact that $\frac{1}{6}$ can be derivatized leaving the vinyl group intact demonstrates that one can potentially prepare a series of organofunctional phosphazene monomers of the type $N_3P_3X_5OCH=CH_2$ starting with $\frac{1}{6}$.

A mixture of bis isomers, 2, which resisted further chromatographic separation, was isolated. The absence of mono or trisubstituted species was confirmed by mass spectrometry. The ³¹P nmr spectrum of 2 (Figure 1) clearly shows the existence of all three positional and geometric isomers of the composition N₃P₃Cl₄(OCH=CH₂)₂. The nmr parameters for each isomer were estimated from the mixture spectrum and used to simulate the individual spectra. The mixture spectrum was matched to the composite of the individual spectra (Figure 1) by varying the contributions of each of the components thus allowing for calculation of the relative concentration of each species. There is a low intensity A₂X spectrum (Figure 1a) in which the A part is in the \equiv PCl₂ chemical shift range while the X part is in the general range found in N₃P₃(OCH=CH₂)₆.

The A_2X spectrum, with A being $\equiv PCl_2$, is consistent only with the geminal isomer. Excluding spirocyclic species, this is the first example of a geminal $N_3P_3Cl_4(OR)_2$ species formed in the reactions of nucleophiles derived from alcohols with $N_3P_3Cl_6$. The non-geminal isomers both exhibit AB_2 spectra (Figure 1 b,c) with identical A regions. In the $B(\equiv PCl(OCH=CH_2))$ region the chemical shifts are slightly different. The relative abundances of each isomer as obtained from the simulation study are 4% geminal and 43 and 53% respectively for the two non-geminal isomers. This characterization of the mixture of bis isomers by high field ^{31}P nmr and simulation studies demonstrates the value of this approach in both qualitative and quantitative studies of phosphazene substitution reactions. The proton nmr spectrum of the mixture, is as expected, complex. In the region associated with H_a (-OCH_2CH_2) there is a triplet 21 in low abundance which is slightly upfield from the H_a resonances for $\equiv PCl(OCH=CH_2)$ environment. The intensity of the triplet increases as one goes through the $N_3P_3Cl_{6-n}$ (OCH=CH_2) series and so it may be taken as an indicator of the amount of species containing the $\equiv P(OCH=CH_2)_2$ center in a mixture.

Given the propensity for trans isomer formation observed in the reactions of cyclotriphosphazenes with alkyl and dialkylamines, 2 , 22 tert-butyl lithium 23 and the trifluoroethoxide ion 6 , it is tempting to suggest that the isomer in greatest abundance is trans $^{-2}$, 4 -N $_{3}$ P $_{3}$ Cl $_{4}$ (OCH=CH $_{2}$) $_{2}$. Any assignment of this type must be considered as tenuous since there is very little knowledge of isomer ratios in the reactions of N $_{3}$ P $_{3}$ Cl $_{6}$ with oxygen bases and the fact that a few reactions of cyclotriphosphazenes with nucleophiles such as phenyl lithium 24 and the phenoxide ion 25 appear to give the cis isomer predominantly. In the case of the bis dimethylaminochlorocyclotriphosphazenes, the 31 P nmr chemical shift for the 27 PClN(CH $_{3}$) $_{2}$ center is more positive for the trans (compared to the cis) isomer. 26 In N $_{3}$ P $_{3}$ Cl $_{4}$ (OCH=CH $_{2}$) $_{2}$, the less abundant non-geminal isomer has the more positive

chemical shift for the \equiv PC1(OCH=CH₂) center. These observations also cast doubt on the suitability of assigning the trans configuration to the more abundant isomer in 2.

The results presented above indicate interesting differences in the reaction pattern in the reactions of $N_3P_3Cl_6$ with $LioCH=CH_2$ and $NaOCH_2CF_3$. In the latter system, the geminal isomer was not observed and the trans isomer was in significantly greater abundance (trans: cis > 5:1). There is not sufficient data to speculate on the reasons for these differences. In particular the roles of the counter ion and the solvent bear further investigation.

The sample, \Im , with the stoichiometry $N_3P_3Cl_3(0CH=CH_2)_3$ has a complex 1H nmr spectrum with evidence for the $\exists P(0CH=CH_2)_2$ center in small amounts. The ^{31}P nmr spectrum of \Im shows evidence for all three isomers (geminal, cis -2,4,6, trans -2,4,6). A doublet of doublets in the $\exists P(0CH=CH_2)_2$ region along with a triplet (center lines of doublet of doublets merged) in the $\exists PCl_2$ region confirm the presence of the geminal (2,2,4) isomer. The $\exists PCl(0CH=CH_2)$ region contains peaks from the geminal isomer, a large singlet corresponding to the cis isomer and an AB_2 pattern assignable to the trans isomer. The overlap of all of these resonances precludes the obtaining of quantitative information concerning isomer ratios. The pattern established at the level of bis substitution is qualitatively maintained i.e. predominantly non-geminal with traces of the geminal product being observed.

The ^{31}P nmr sample of 4 , the tetrakis sample, again indicates the existence of all three isomers. The geminal isomer is in very low abundance and is characterized by an AX₂ spectrum with A in the $\equiv PC1_2$ and X in the $\equiv P(OCH=CH_2)$ region. There are two sets of closely spaced A_2X spectra covering the $\equiv PC1(OCH=CH_2)_2$ and $\equiv P(OCH=CH_2)_2$ regions which correspond to the non-geminal cis and trans isomers in nearly equal amounts.

The pentakis derivative, ξ , exhibits an AB_2 ^{31}P nmr spectrum which is approaching AX_2 . In aminophosphazene derivatives, materials which appear to be $N_3P_3Cl(NR_2)_5$ are often hydrochlorides of $N_3P_3(NR_2)_6^2$ so we carried out the reaction of ξ with dimethylamine to yield $N_3P_3N(CH_3)_2(OCH=CH_2)_5$ thus providing chemical structure proof of the proposed formulation of ξ .

The 31 P nmr spectrum of the hexa substituted material, 6, has the expected singlet in the \equiv P(OCH=CH₂)₂ region. The 1 H nmr spectrum shows a curious anomaly in that there is an increase in the number of lines in the H_a region over what is observed in $\frac{1}{4}$. The origins of this complication are unclear but it does suggest different environments for the exocyclic substituents.

In summary, it has been shown that the reaction of the lithium enolate of acetaldehyde with $N_3P_3Cl_6$ leads to the complete series of compounds of the type $N_3P_3Cl_{6-n}$ (OCH=CH₂)_n. The non-geminal pathway is favored. This new, and to date most complete, series of organofunctional phosphazenes can be expected to form the basis of extensive new incorporation of cyclophosphazenes into polymeric systems. Of particular interest is the possibility that the non-geminal species will be reagents for novel cross-linking and related reactions. Work along these lines is currently in progress in our laboratory.

Acknowledgements. This work was supported in part by the Office of Naval Research.

We also wish to thank Professor C. H. Bushweller for providing
the modified DNMR3 program and Mr. R. Bright and Mr. Christopher
Rithner for carrying out the simulation studies.
